

Datawarehousing With IBM Cloud Db2 Warehouse

Phase 4 : Development part 2

Continue building the data warehouse by implementing ETL Processes and enabling data exploration.

ETL Process in Data warehouse

ETL stands for Extract, Transform, Load and it is a process used in data warehousing to extract data from various sources, transform it into a format suitable for loading into a data warehouse, and then load it into the warehouse.

1. Extract: The first stage in the ETL process is to extract data from various sources such as transactional systems, spreadsheets, and flat files. This step

involves reading data from the source systems and storing it in a staging area.

2.Transform: In this stage, the extracted data is transformed into a format that is suitable for loading into the data warehouse. This may involve cleaning and validating the data, converting data types, combining data from multiple sources, and creating new data fields.

3. Load: After the data is transformed, it is loaded into the data warehouse. This step involves creating the physical data structures and loading the data into the warehouse.

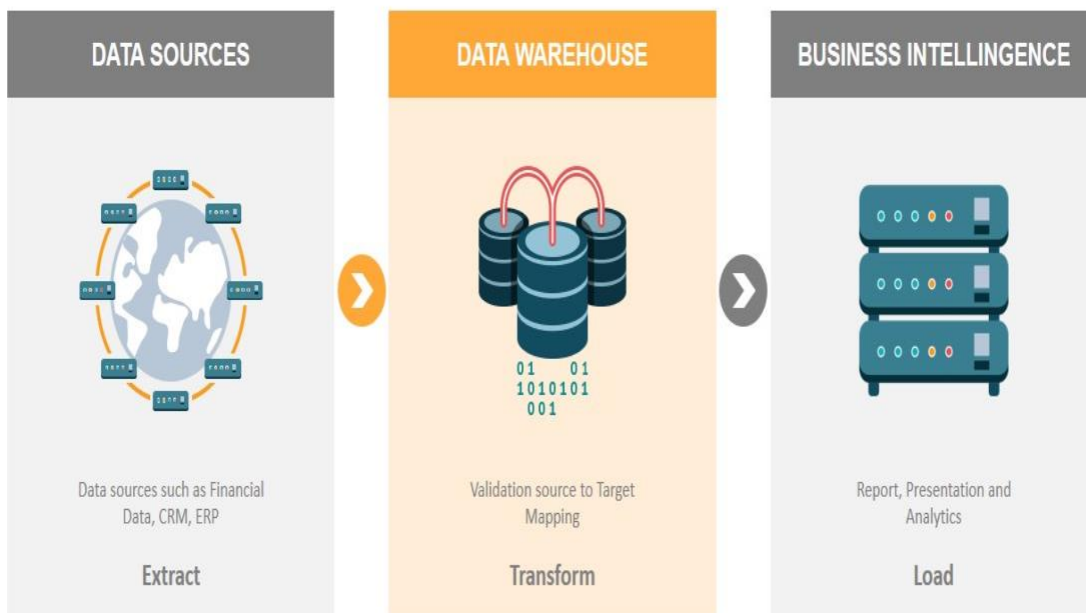

ETL Tools :

Most commonly used ETL tools are Hevo, Sybase, Oracle Warehouse builder, CloverETL, and MarkLogic.

Data Warehouse :

Most commonly used Data Warehouses are Snowflake, Redshift, BigQuery, and Firebolt.

ETL PROCESS

Advantages of ETL process in data warehousing:

1. Improved data quality : ETL process ensures that the data in the data warehouse is accurate, complete, and up-to-date.

2. Better data integration : ETL process helps to integrate data from multiple sources and systems, making it more accessible and usable.

3. Increased data security : ETL process can help to improve data security by controlling access to the data warehouse and ensuring that only authorized users can access the data.

4. Improved scalability : ETL process can help to improve scalability by providing a way to manage and analyze large amounts of data.

5. Increased automation : ETL tools and technologies can automate and simplify the ETL process, reducing the time and effort required to load and update data in the warehouse.

Disadvantages of ETL process in data warehousing:

- 1. High cost :** ETL process can be expensive to implement and maintain, especially for organizations with limited resources.
- 2. Complexity :** ETL process can be complex and difficult to implement, especially for organizations that lack the necessary expertise or resources.
- 3. Limited flexibility :** ETL process can be limited in terms of flexibility, as it may not

be able to handle unstructured data or real-time data streams.

4. Limited scalability : ETL process can be limited in terms of scalability, as it may not be able to handle very large amounts of data.

5. Data privacy concerns : ETL process can raise concerns about data privacy, as large amounts of data are collected, stored, and analyzed.

SELECT column1, column2

FROM source_table

WHERE condition;

Transform: Apply transformations to the extracted data.

Extract: Retrieve data from the source.

UPDATE target_table

SET transformed_column =
some_transformation_function(original_column);

Load: Load the transformed data into the target database.

**INSERT INTO target_table (column1,
column2)**

VALUES (value1, value2);

Before Dataset

ETL process

```
# Example Python script for ETL using pandas
import pandas as pd

# Extract data from source (e.g., CSV file)
data = pd.read_csv('source_data.csv')

# Transform data (e.g., clean, transform, enrich)
transformed_data = data[['customer_id', 'customer_name', 'email']]

# Load data into Db2 Warehouse
from sqlalchemy import create_engine

engine = create_engine('db2://username:password@hostname:port/database_name')
transformed_data.to_sql('customers', engine, if_exists='replace', index=False)
```

Data Exploration

```
-- Example SQL query to analyze total order amounts per customer
SELECT c.customer_name, SUM(o.total_amount) AS total_spent
FROM customers c
JOIN orders o ON c.customer_id = o.customer_id
GROUP BY c.customer_name
ORDER BY total_spent DESC;
```

SQL Queries :

```
SELECT Customer id , Customer Name  
FROM Customer ;
```

```
INSERT INTO Customers (CustomerName,  
ContactName, Initial , Phone no, Date of  
Birth, Email id)
```

```
UPDATE Customers  
  
SET CustomerName = 'Afra', Sex= 'Female'  
  
WHERE CustomerID = 19;
```

```
DELETE FROM Customers WHERE  
  
CustomerName='Midhuna';
```

```
CREATE TABLE Customers(  
  
Customer Id Int,  
  
Customer Name Varchar(20),  
  
Initial Varchar(10),  
  
Sex Varchar (20),
```

Email id Varchar(20),
Phone no Number,
Date of Birth Number,
);

After writing the SQL Queries the final output is

| | A | B | C | D |
